

Grassland degradation – a global perspective

The case of greenhouse gas mitigation

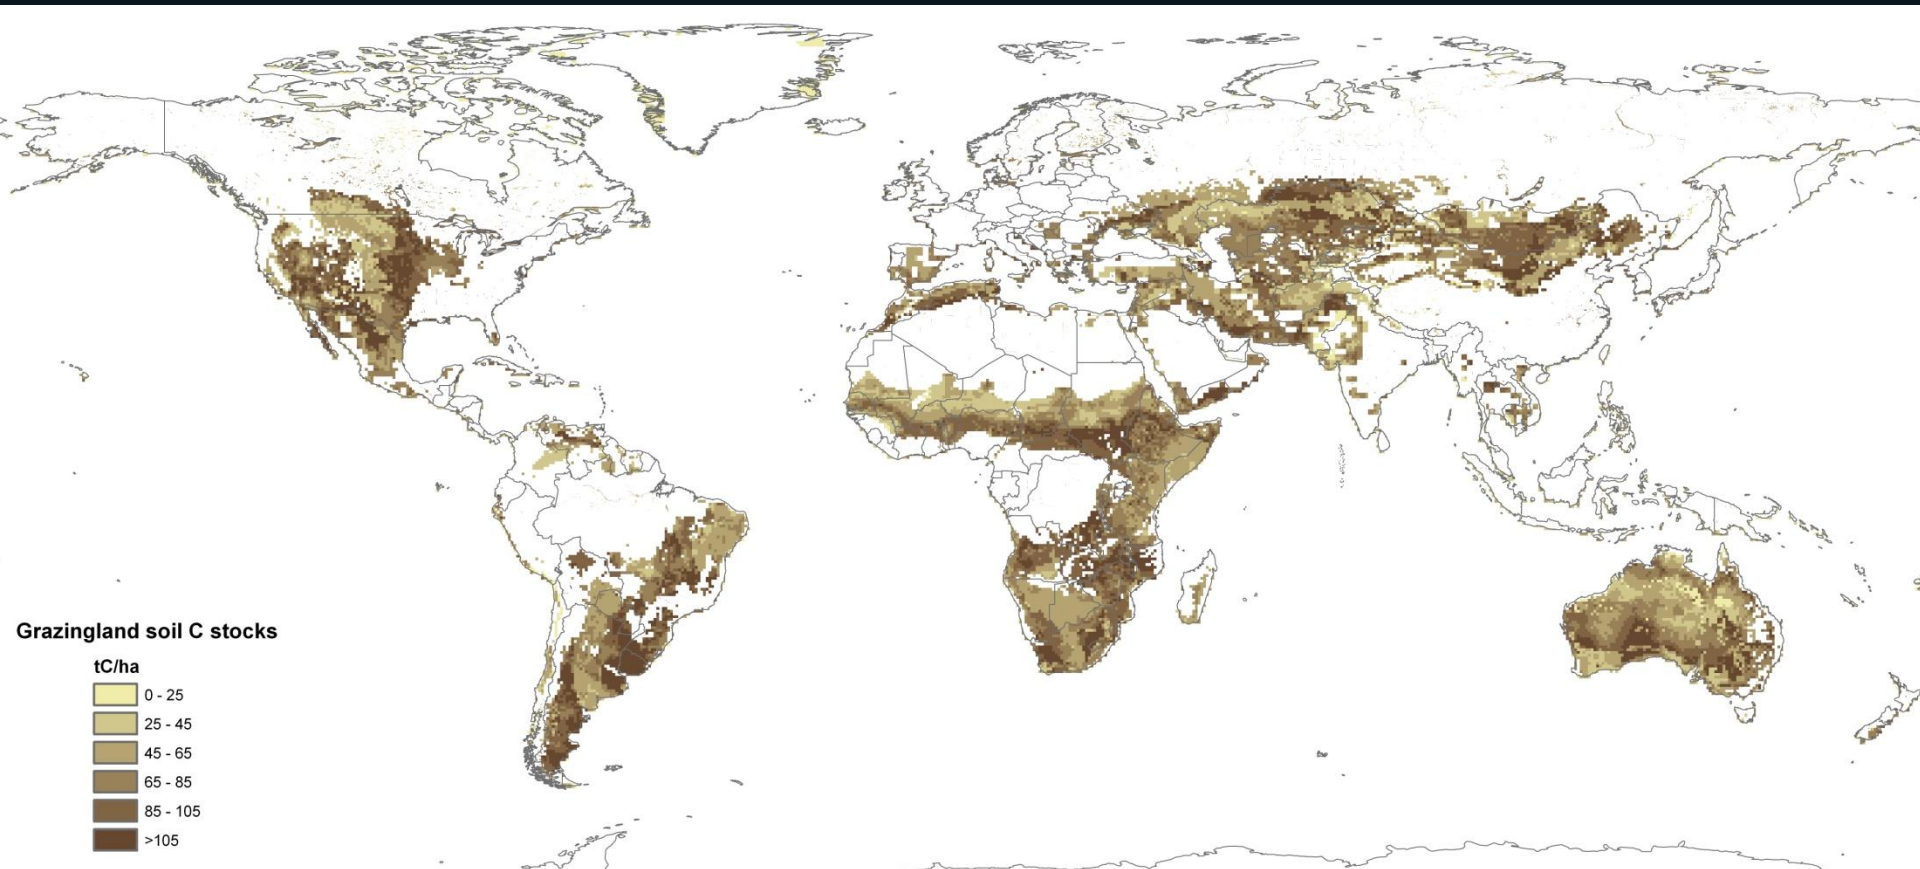

Richard Conant

Colorado State University

and

International Livestock Research Institute

Carbon flow in grassland ecosystems

Carbon stocks in grassland ecosystems

1. Grassland soil C stocks are substantial.

Poor grassland management practices

Overgrazing

Low fertility

Erosion

Inefficient forage use

**Soil organic
matter**

Improved management practices

Reverse overgrazing

Sowing legumes/
improved species

**Soil organic
matter**

Irrigation

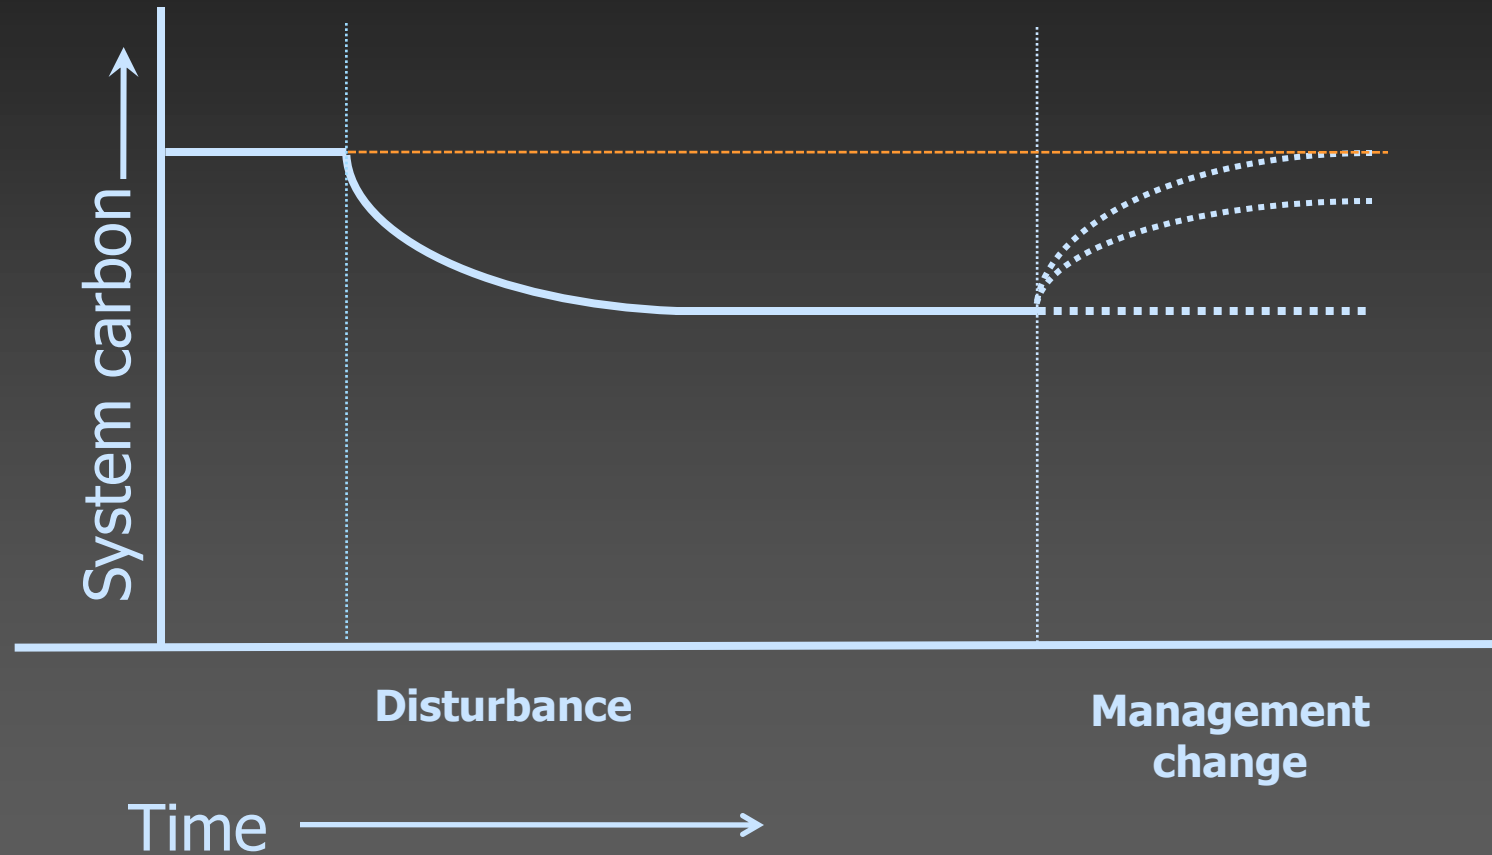

Fertilization

Carbon stocks in grassland ecosystems

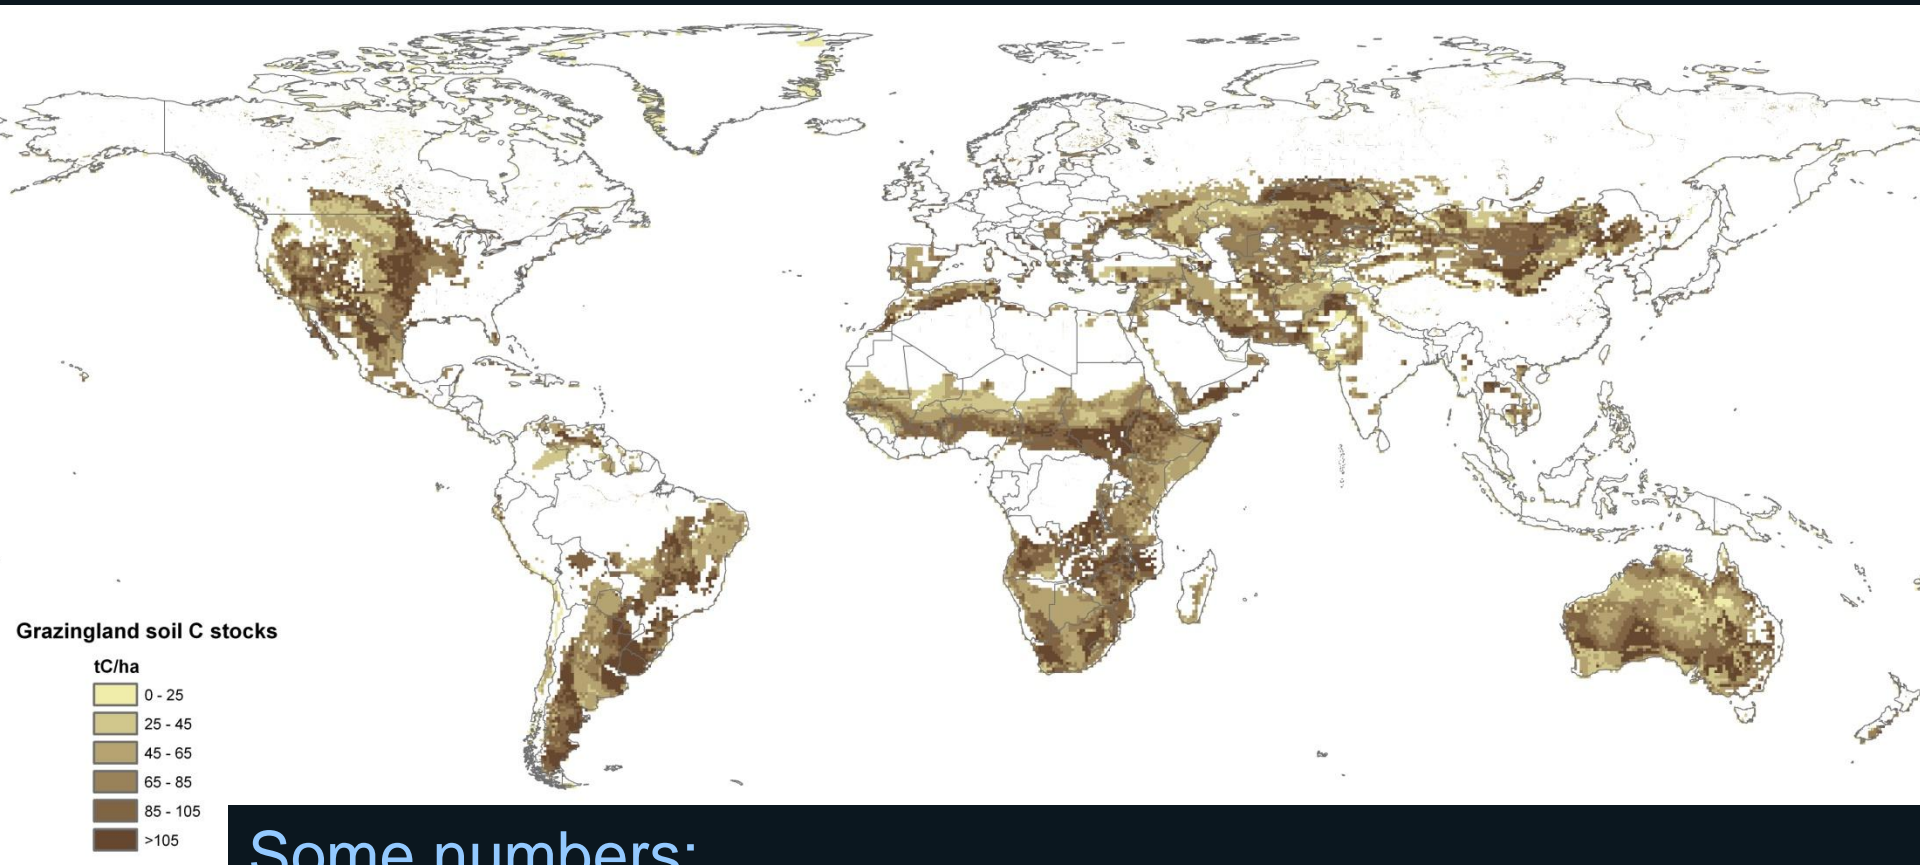

– *conceptual framework*

Carbon stocks in grassland ecosystems

1. Grassland soil C stocks are substantial.
2. Management impacts carbon stocks – C stocks are susceptible to loss
3. Carbon lost from grassland systems can be regained through changes in management
4. Improved management practices can increase soil carbon stocks

Carbon flow in grassland ecosystems

Some numbers:

5.1Bha → 730Mha converted to cropland

~415Pg C (in top 20cm) → ~at least 30 PgC lost due to conversion to cropland

Carbon stocks in grassland ecosystems

— *technical potential for sequestration is large*

Carbon stocks in grassland ecosystems

What do we know?

1. Grassland soil C stocks are substantial.
2. Management impacts carbon stocks – C stocks are susceptible to loss
3. Carbon lost from grassland systems can be regained through changes in management
4. Improved management practices can increase soil carbon stocks
5. Technical potential for sequestration in grasslands is large

Carbon stocks in grassland ecosystems

— *limited knowledge about costs/benefits*

Exhibit 1

Global GHG abatement cost curve beyond business-as-usual – 2030

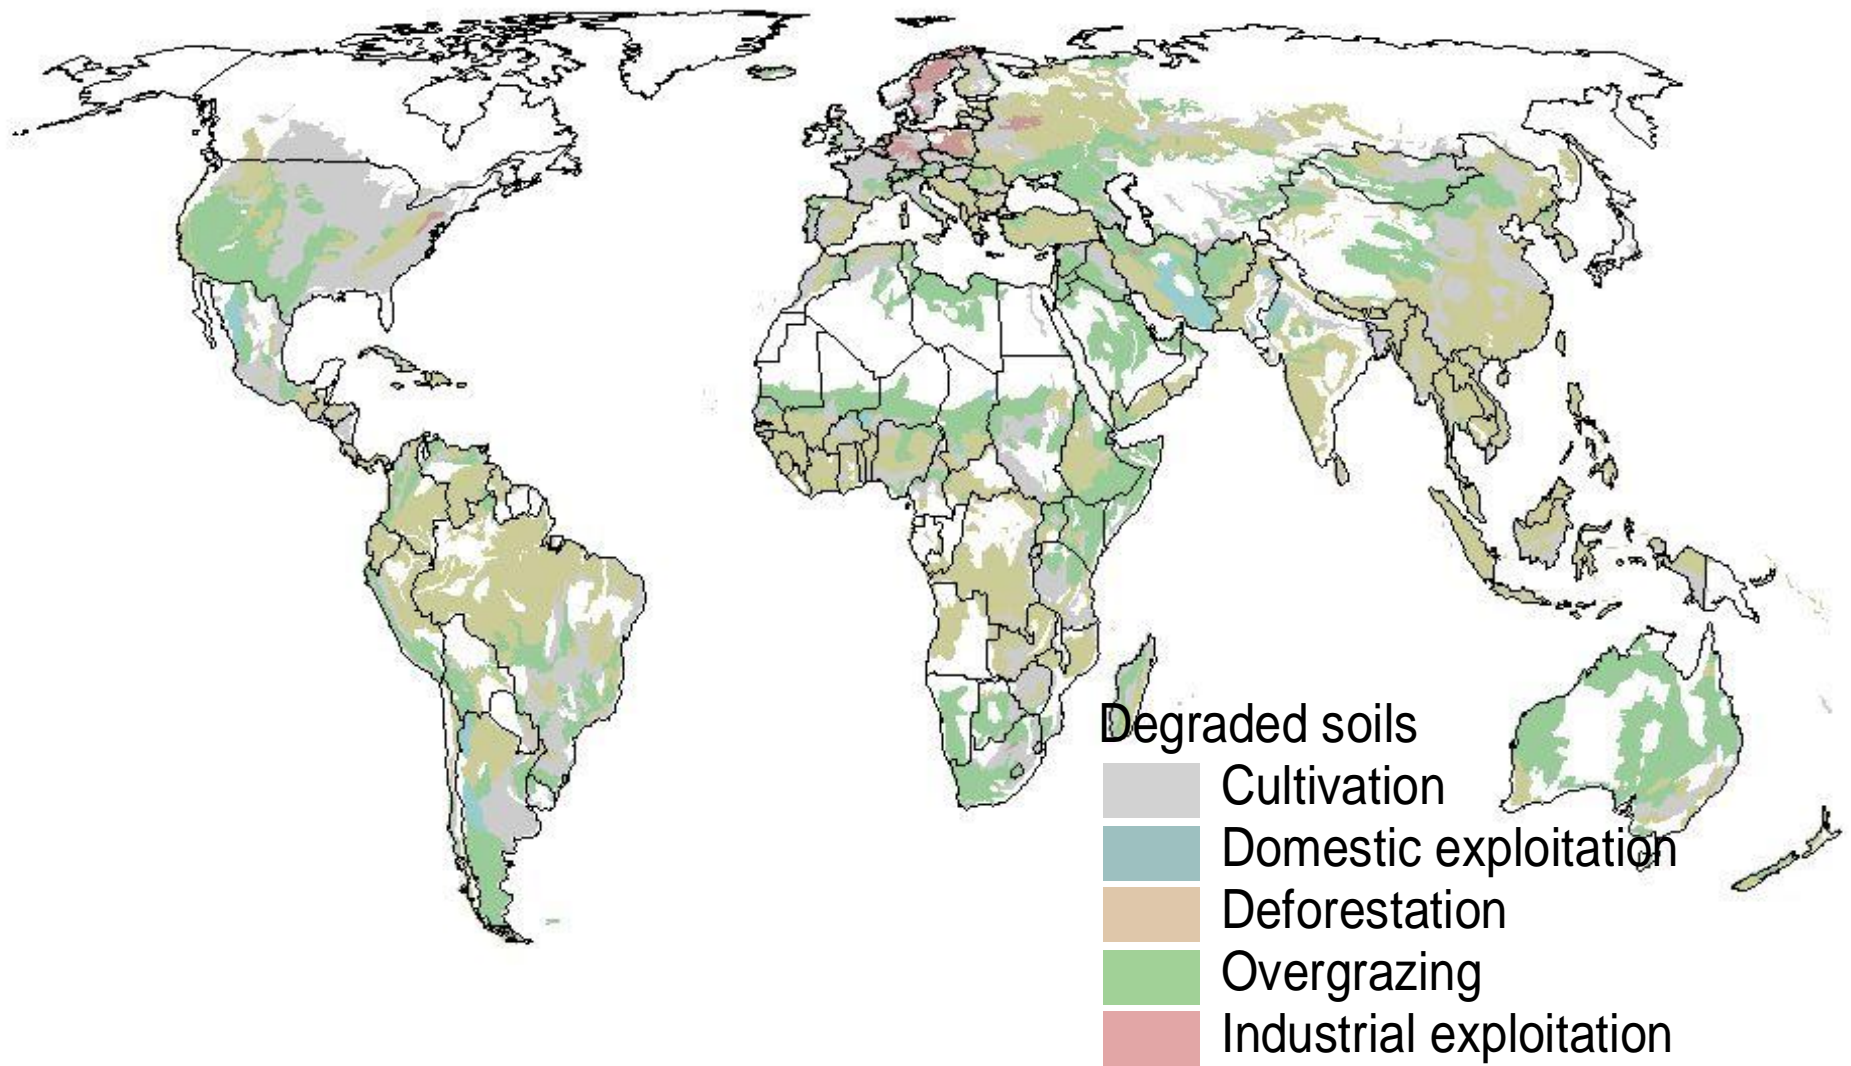

Note: The curve presents an estimate of the maximum potential of all technical GHG abatement measures below €60 per tCO₂e if each lever was pursued aggressively. It is not a forecast of what role different abatement measures and technologies will play.

Carbon stocks in grassland ecosystems

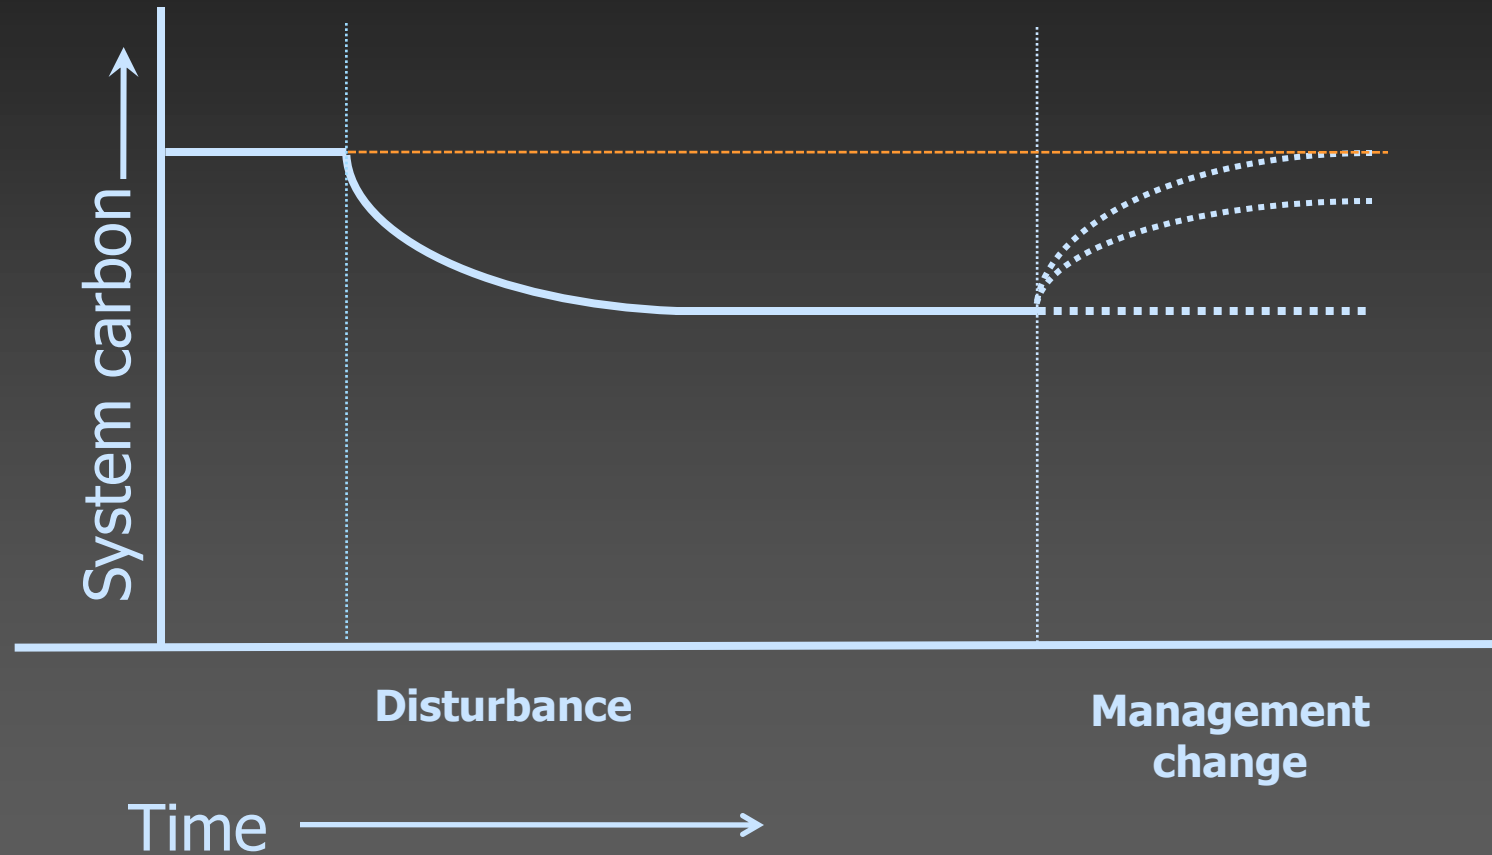

– *how to assess global potential?*

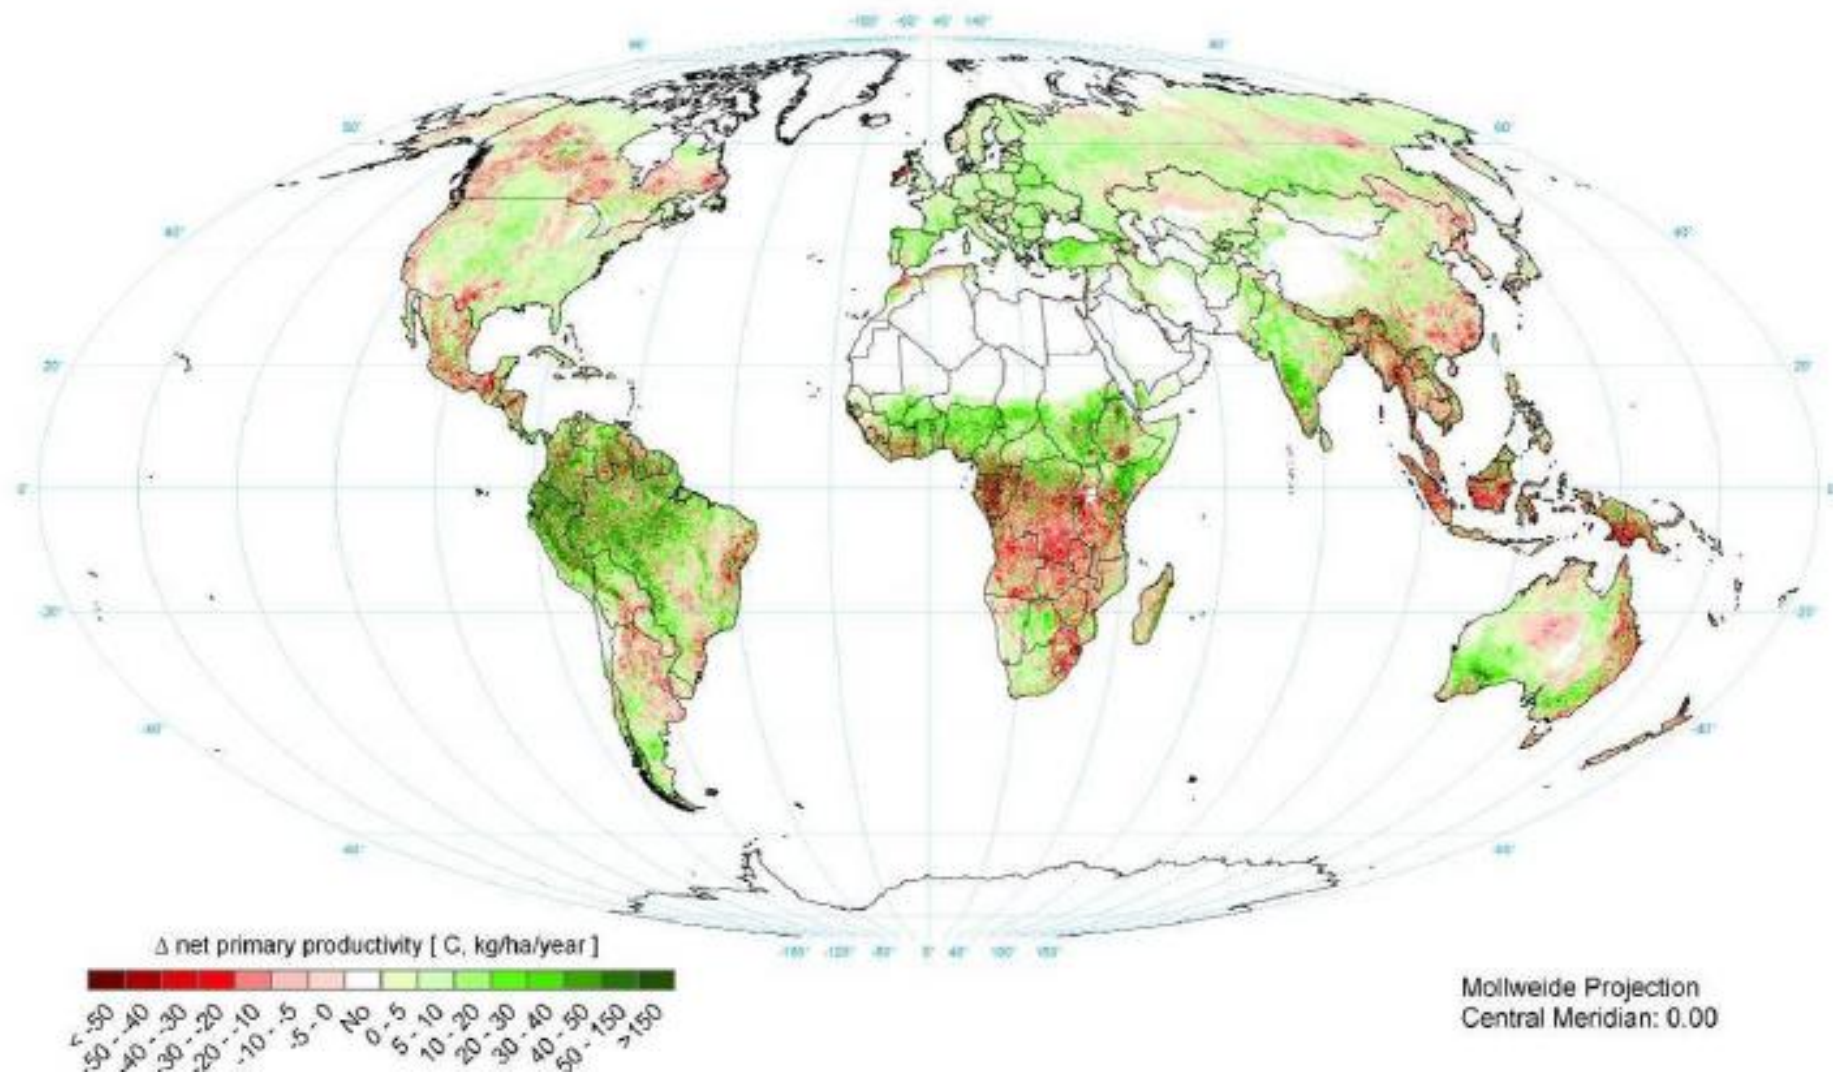

Carbon stocks in grassland ecosystems

– *how to assess global potential?*

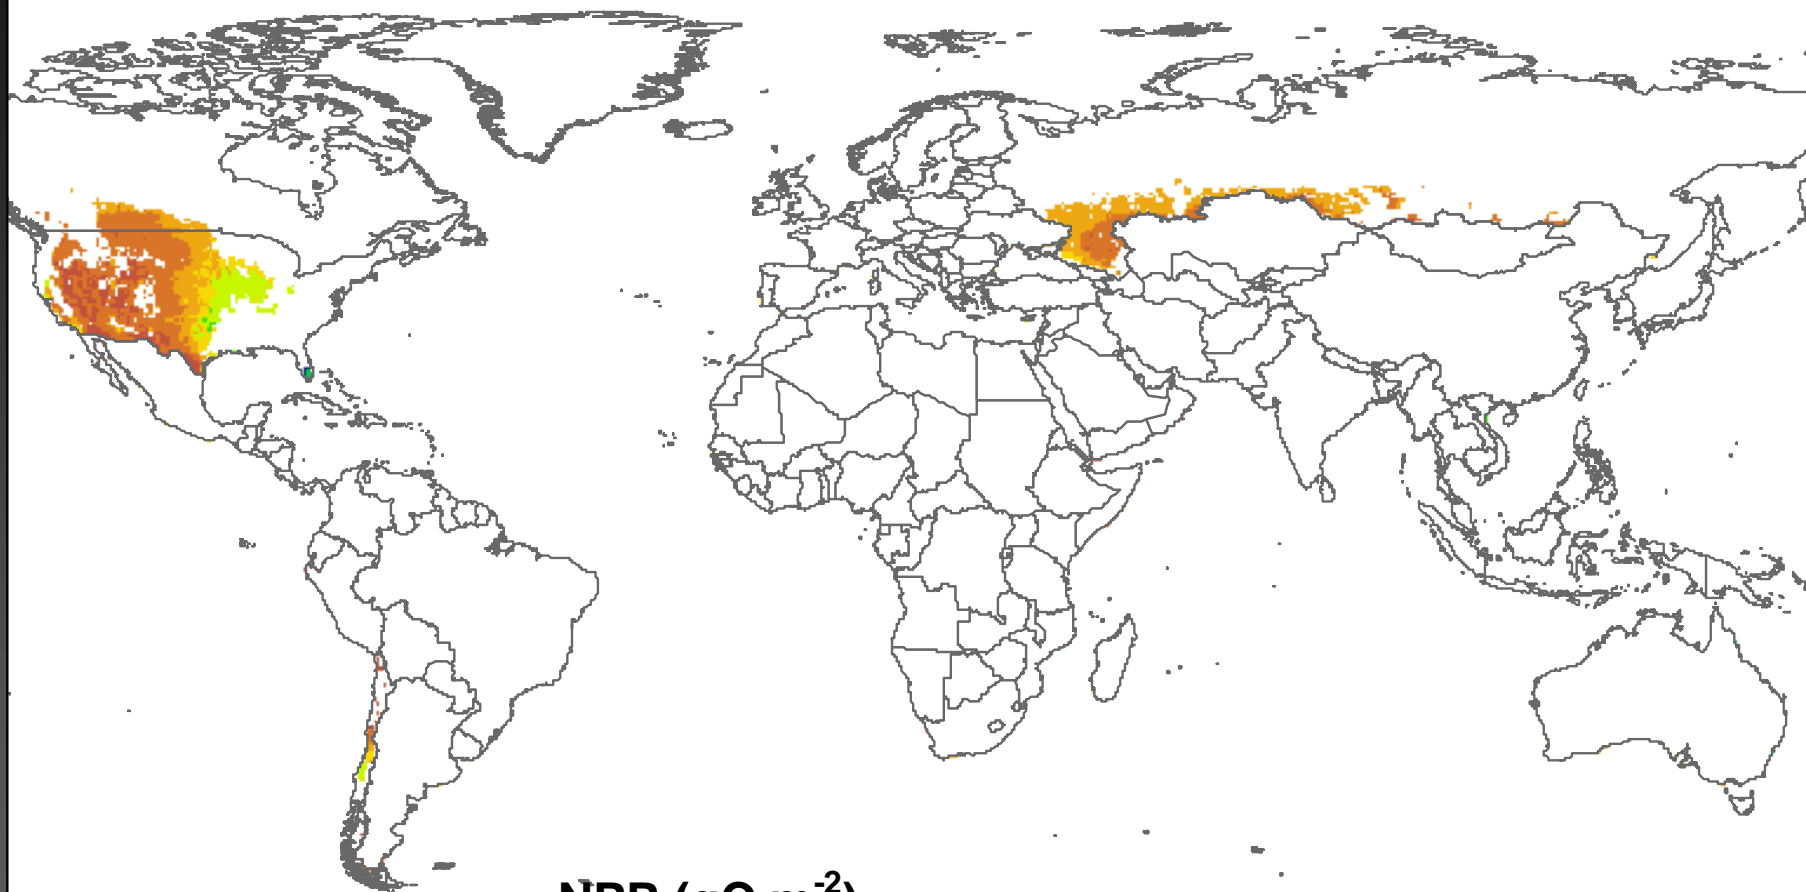

Carbon stocks in grassland ecosystems

– *how to assess global potential?*

NPP_{sim} at grazing level that best matched LADA NPP

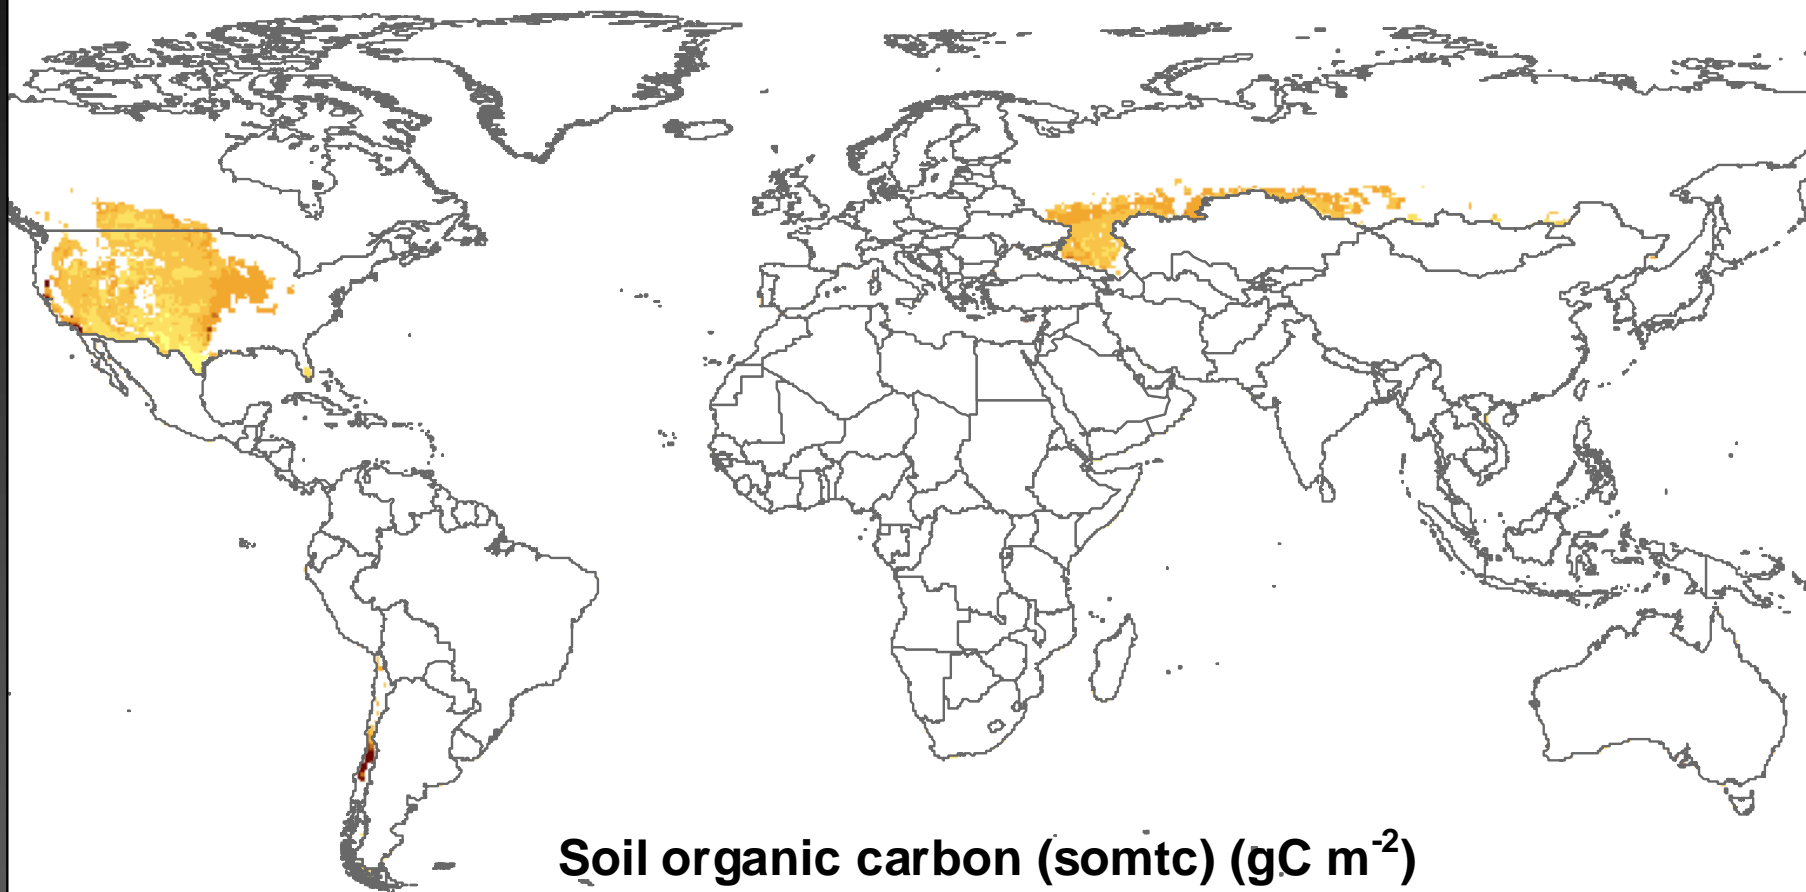

NPP (gC m⁻²)

0 - 75
76 - 150
151 - 225
226 - 300
301 - 375
376 - 450
451 - 525
526 - 600
601 - 675
676 - 925

Soil organic carbon (somt) at grazing level that best matched LADA NPP

Soil organic carbon (somt) (gC m⁻²)

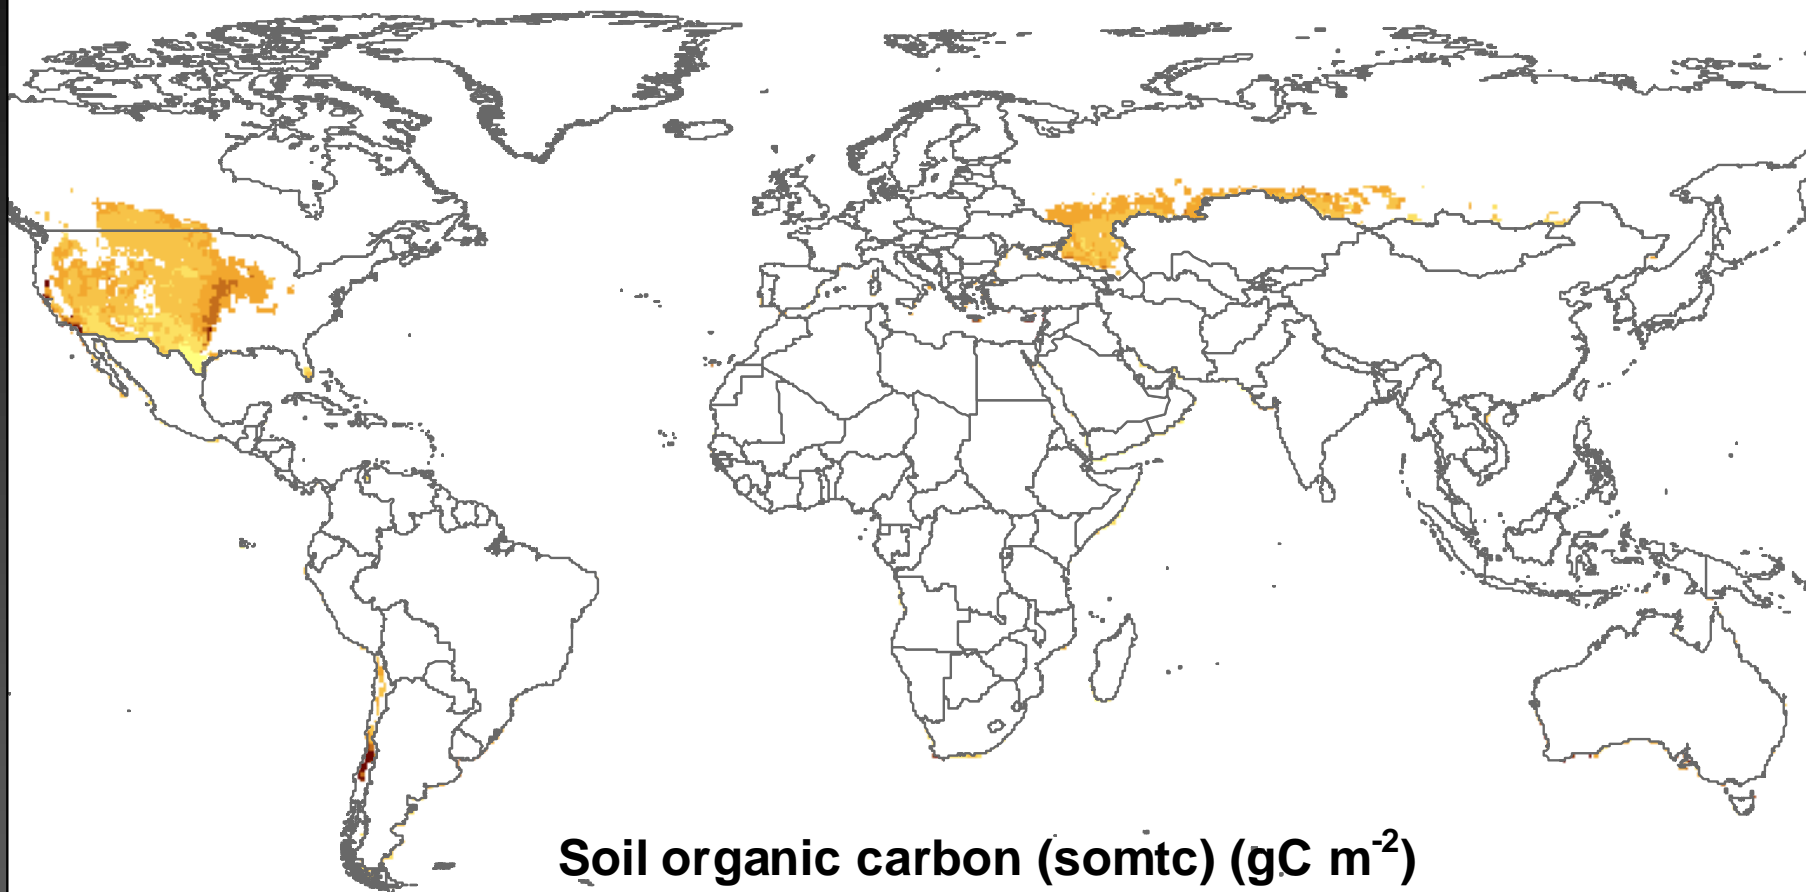

< 1,500
1,500 - 3,000
3,000 - 4,500
4,500 - 6,000
6,000 - 7,500
7,500 - 9,000
> 9,000

Carbon stocks in grassland ecosystems

– *how to assess global potential?*

Soil organic carbon (somt) at grazing level with maximum NPP

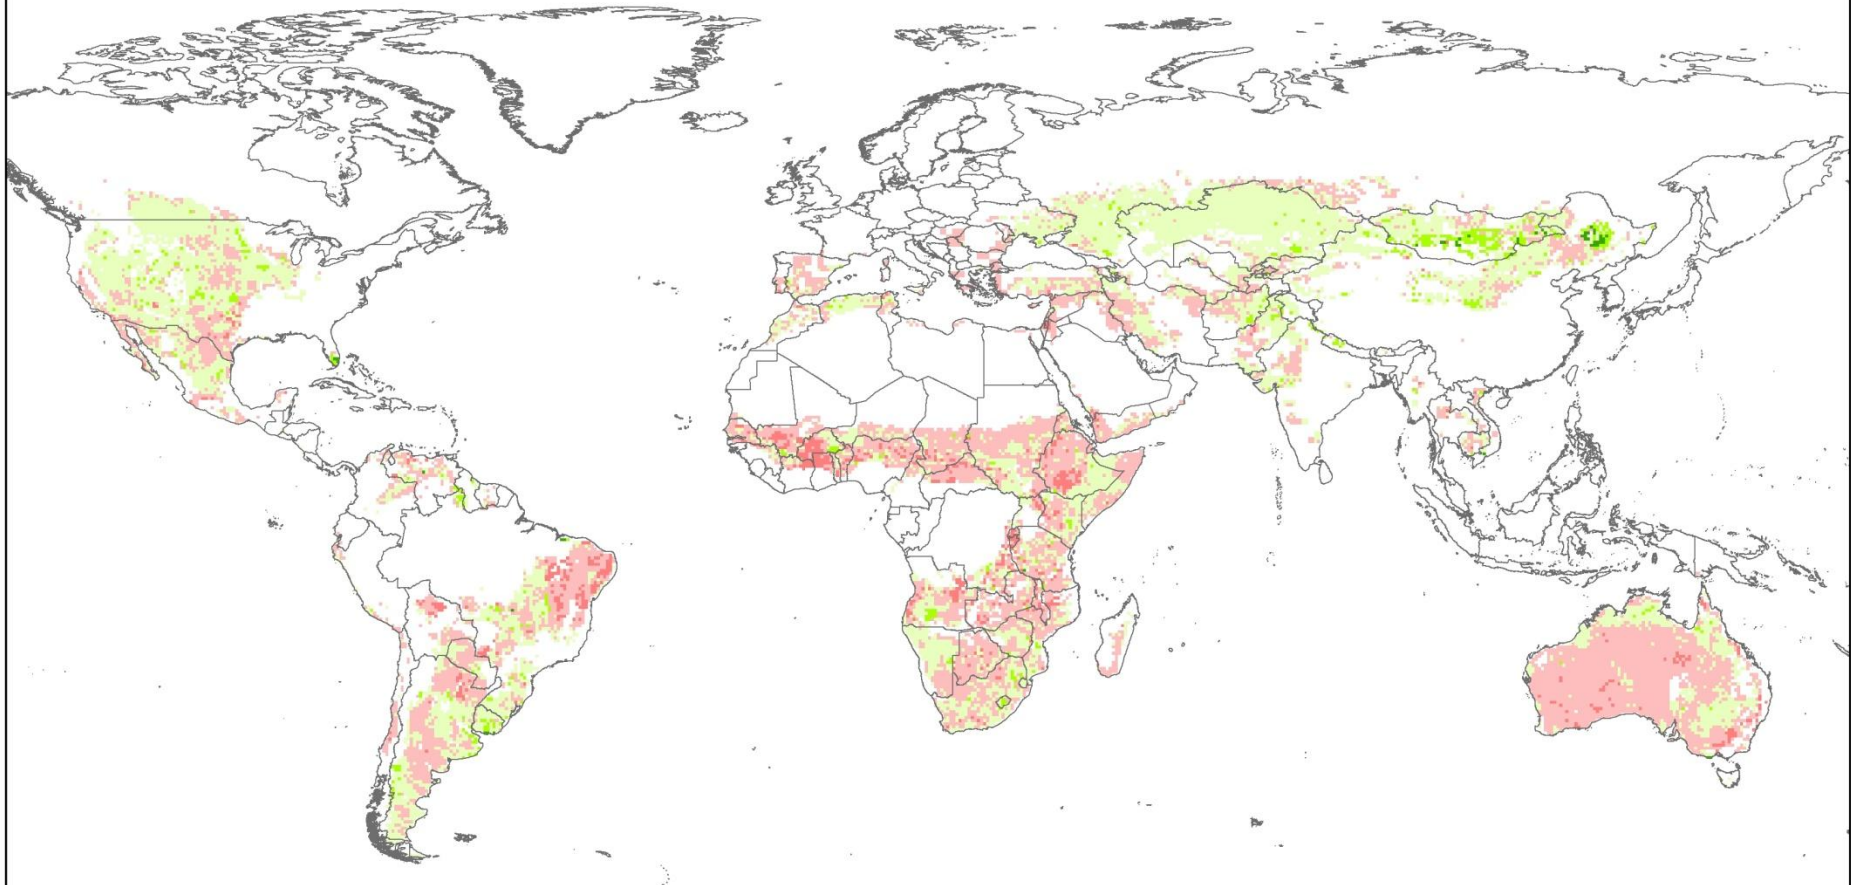

Soil organic carbon (somt) (gC m⁻²)

< 1,500
1,500 - 3,000
3,000 - 4,500
4,500 - 6,000
6,000 - 7,500
7,500 - 9,000
> 9,000

Soil organic carbon difference
Transition from LADA baseline to max NPP
(1986 – 2006)

Soil organic matter (gC m⁻²)

Carbon stocks in grassland ecosystems

Net C stocks don't always decline

Restoring value to grasslands

– *quantifying benefits*

1. The potential for carbon sequestration driven by restoration of degraded grasslands is substantial
2. Opportunities vary as a function of type and severity of degradation.
3. Restoration seems likely to be very challenging in some rangeland – carbon benefits may be small (even negative), costly, and slow to realize.
